ABSTRACT

There are substantial differences in the interests of men and women, reflected by their answers to vocational interest inventories. These differences are not trivial; they persist even in samples of men and women selected for occupational equivalence. The content of the sex differences is diverse. Lumping these differences together into one empirical scoring scale and labeling it "masculinity/femininity" creates more interpretative problems than it solves. The best way to proceed now is to stop using M-F scales and concentrate instead on homogeneous scales -- such as scales for mechanical interests and artistic interests -- so that, for example, a person with strong mechanical interests and weak artistic interests can be described exactly that way with no implication that this pattern connotes masculinity. (Author/CK)

The SVIB M-F Scale: Must we ignore

feminine aversions for carburetors?*

News Item: A New Ulm, Minnesota mother was trying to fix her lawnmower. As she was trying to find the lever onto which to hook the speed control wire, her 8-year-old daughter happened by and asked what she was looking for. "The governor", the woman said. After a puzzled pause, the daughter asked, "How do you think he got in there?"

Minneapolis Tribune, July 5, 1972

I am going to discuss M-F scales from the viewpoint of vocational interests. I would like to make four main points:

First, there are substantial differences in the interests of men and women, reflected by their answers to vocational interest inventories. These differences are not trivial, they persist even in samples of men and women selected for occupational equivalence, and to ignore them would be misleading.

Second, the content of the differences between men and women is diverse and not easy to summarize. While there are some major themes -- men have stronger mechanical interests, women stronger artistic interests -- still, there are many other contrasts that don't fit into neat categories.

Third, lumping these differences together into one empirical scoring scale and labeling it "Masculinity-Femininity" creates more interpretative problems than it solves, especially as these labels have so much surplus meaning.

Fourth, we should stop using M-F scales and concentrate instead on homogeneous scales so that, for example, a person with strong mechanical interests and weak artistic interests can be described in exactly that way without implying that this pattern connotes masculinity.

TM 002 877

Because this topic is so emotion-laden, I would like to stay close to the data; let me begin by showing you some statistics on M-F differences. These were taken from samples tested with the SVIB; as you know, in this inventory, the person is given a long list of occupations or occupational activities, and asked to respond "Like", "Indifferent", or "Dislike" to each of them. The responses can be analyzed by tallying the percent response to each choice for each item, and comparing these percentages across samples. Experience has taught us that differences greater than 18-20 % are important.

INSERT TABLE 1 ABOUT HERE

The second page of the handout, Table 1, gives data for the item, "Adjust a carburetor" for several samples. The first is an eighth grade class from a typical suburban school; the boys reported much more attraction than the girls for carburetors, which is fascinating as only a few students of either sex at this age have more than a vague idea of what a carburetor is.

The second sample, a ninth grade class drawn from a more rural school, shows an even greater difference between the sexes.

The third sample includes 45 married couples, and the differential attraction for carburetors is again obvious.

At the bottom of the page are listed the response percentages to this item for several samples of Men-In-General, which are the samples used to establish the base rate popularity of items. Interestingly, for the last 30 years, the carburetor item has split the male population roughly into thirds. No comparable data for Women-In-General are available because this item has never appeared on the women's form, a flaw that will be corrected next year when the new combined version of the Strong will appear, suitable for either sex.

INSERT TABLE 2 ABOUT HERE

However, the response percentages for both sexes are available for a similar item "Operating Machinery"; they are shown in Table 2. Again, the sex differential is obvious; roughly half of the men, compared with a quarter of the women, answered "Like" to this item.

INSERT TABLE 3 ABOUT HERE

The male-female difference in mechanical interests is even more vividly shown in the next table -- Table 3 -- which has the distribution of "Like" percentages to the item "Operating Machinery" for over 300 occupational samples. Male samples are designated by X's, female samples by O's. Although the distributions overlap, the separation between the sexes is obvious and this isn't even one of the best M-F items.

The samples with the highest and lowest percentages for each sex are listed at the top of the table, and make interesting scanning.

This table, incidentally, is a good illustration of the way that interest inventory items spread occupations out over wide ranges -- for this item, from 4 to 97 percent.

Most of these statistics are from individuals in "typical" sex roles; thus, the differences between the sexes may be due mainly to cultural pressure, and they might disappear if we could compare men and women who have made equivalent

career choices. In an attempt to do this, 17 pairs of samples of men and women from the same occupation have been selected; that is, one pair of samples is male and female artists, another pair is male and female life insurance sales personnel, another pair is male and female psychologists, and so forth. These samples, collected in 1967-69 for the restandardization of the Strong Blank, are large -- usually 200 or 300 of each sex -- and well selected; every individual has had at least three years of experience, each one reported that they liked their job, and wherever appropriate, all had the necessary degree or certification in their field.

These samples can be used to see if the contrasts in interests between men and women disappear when the samples are drawn from the same occupations. There are three possibilities:

1. Men and women in the same occupations have the same interests.
2. They have different interests, and the differences are specific to each occupation.
3. They have different interests, and the differences are constant across all occupations.

INSERT TABLE 4 ABOUT HERE

To study this point, all SVIE items showing a 20 percent or greater difference between Men and Women-In-General are listed here. For the most part, these constitute the SVIE M-F scale. These items show large response differences between men and women at large; the question here is whether these differences also appear between men and women in the same occupation.

The numbers in the table show the percentage difference between the occupational samples in the response "Like" to that item. For example, the first line of numbers shows the difference between men and women in the "Like" response to the item "Decorate a room with flowers". The first column shows the MIG-WIG comparison, a whopping 61 percent. The top line reports the analogous figure for male and female artists, bankers, and so forth. The last column shows the average difference for this item across these samples. The first and last columns are the important ones for they show the comparison between men and women-in-general, and men and women when occupation is held constant. There is a lot of data in this table, which stretches over two pages, and you may want to study it more closely, at your leisure.

With a very few exceptions, which are not included in this table, the differences in interests between men and women are constant across all occupations; no occupation is free of these differences, nor does any occupation studied here have any novel pattern of differences between men and women that does not appear in any other occupation.

This finding has several important implications: first, these data demonstrate that the M-F difference does not go away when one controls for occupation tested.

Second, obviously, sex cannot be ignored in norming interest inventories. The differences are real, they can be identified empirically, and to ignore them would introduce error variance in the system.

Third, the content of the differences is not spread all over the domain of interests; they tend to be concentrated in artistic activities, favored by women, and mechanical activities, favored by men. There are other lesser themes, but these are the main two.

Fourth, a final implication comes from trying to understand the bigger picture of men, women and occupations. With these basic differences, can we expect men and women to enter all jobs in equal numbers? I think not. In the foreseeable future, for example, there will be fewer women than men who like to monkey around with carburetors. Those women who wish to should be allowed to -- most emphatically there should be no artificial barriers in their way to equal employment -- but most will not want to and companies who hire lots of carburetor repairmen shouldn't be faulted simply because their work force is not 50-50, men-women.

The information presented thus far has focused mainly on the extreme cases in the SVIB items; now I would like to show you some data that more accurately represent the general situation across several areas of interest.

I have taken advantage of John Holland's occupational classification theory for this; he believes the world is divided up into six types of people: Realistic, such as farmers and engineers; Investigative, mainly scientists; Artistic, artists and musicians; Social, social workers and teachers; Enterprising, mainly salesmen; Conventional, such as bookkeepers and accountants.

INSERT TABLE 5 ABOUT HERE

One item from each of these areas is listed in Table 5 with the L-I-D percentages for the Men and Women-In-General samples. A quick scan of these data shows that the size of the differences between the sexes varies over these content areas. The men show a slight but insignificant edge in the Realistic area and a mild edge in the Investigative area. The women are substantially higher in the Artistic and Social areas and the sexes are roughly equal in the

Enterprising and Conventional areas, though women report more distaste for managing an office.

These data provide a more accurate picture of the nature and size of the M-F differences. Again, they clearly exist, and they are not trivial. Still, to describe them as M-F differences -- as opposed to, say, artistic interests -- confuses the issues, especially at this point in history. (My wife incidentally interprets these data as showing men are occupationally rigid, and in need of liberation. Says she, "Women answer 'Like' almost as often as men in all these areas, and much more often in a couple. Obviously men are not as willing to consider the wide range of possibilities.")

As I mentioned earlier, within the next year, a new version of the Strong will appear, designed for both men and women. There will be some substantial changes on the profile, one of them being the elimination of the M-F scale which -- in the measurement of interests -- has outlived its usefulness, if indeed it ever had any.

HANDOUT

The SVIB Masculinity-Femininity Scale: Must we ignore feminine aversions for carburetors?*

David P. Campbell
University of Minnesota

ABSTRACT

There are substantial differences in the interests of men and women, reflected by their answers to vocational interest inventories. These differences are not trivial, they persist even in samples of men and women selected for occupational equivalence, and to ignore them would be to introduce considerable error into the scoring of these inventories.

The content of the sex differences is diverse and not easy to summarize. While there are some major themes -- men have stronger mechanical interests, women artistic interests -- there are many other contrasts that don't fit into neat categories.

Lumping these differences together into one empirical scoring scale and labeling it "Masculinity-Femininity" creates more interpretative problems than it solves, especially as these labels have so much surplus meaning.

The best way to proceed now is to stop using M-F scales and concentrate instead on homogeneous scales -- such as scales for mechanical interests and artistic interests -- so that, for example, a person with strong mechanical interests and weak artistic interests can be described in exactly that way with no implication that this pattern connotes masculinity.
